Interview Task

Property Finder – Tech Interview

Congratulations! 🥳
This is a **take-home coding exercise** for the Property Finder iOS team.
You have **up to 3 days** to work through the tasks below at your own pace.

Our idea is to evaluate your working style:

- **How you structure your code**
- **How you are tackling specific tasks**

We put together a very lite version of our beloved Property Finder application, with a simple backend functionality, tracking, logging, and all the other stuff... just basic UI of two out of many screens of the actual application.

Table of Contents

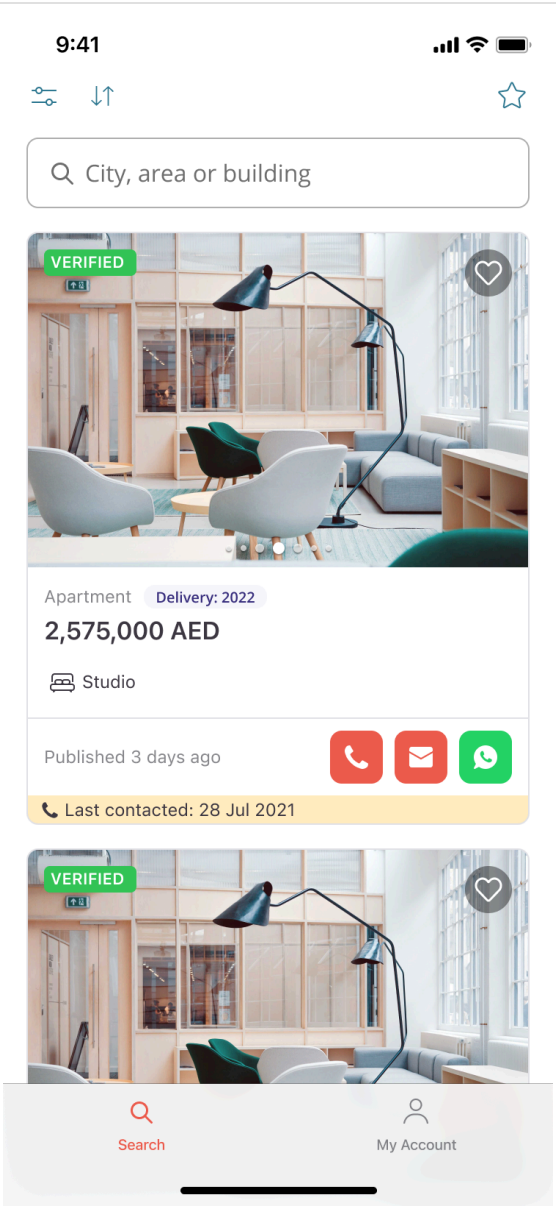

- Task 1 – Rebuild the following UI in SwiftUI
- Task 2 – Fetch listings and populate the Search screen
- Task 3 – Favourites and filtering
- Bonus Task – Refactor the Settings screen
- Sending the project file back in

Task 1 – Rebuild the following UI in SwiftUI

Notes
- The list should scroll beneath the search bar
- Each button should only print a short statement to the console
- The carousel images are in Assets.xcassets

Design Remarks
- Corner Radius: `Multiples of 4`
- Paddings: `Multiples of 4`
- Spacings: `Multiples of 4`

Font Remarks
- Tags: `.caption2`
- "2,575,000 AED": `.headline`
- Everything else: `.caption`

Task 2 – Fetch listings and populate the Search screen

In Task 1 you rebuilt the UI of the search screen. In this task, you will **back it with real data.**

We host a JSON payload that represents the list of properties shown in the screenshot at:

`https://simplejsoncms.com/api/m6nfoc4jlw`

Your job is to:

- **Fetch the data** from the hosted endpoint using `URLSession`
- **Populate the Search screen** with the decoded listings, including tags, meta information, and carousel images

JSON shape

▶ Click to view JSON contract

Notes

- **Studio vs bedrooms:** `bedrooms: null` represents a Studio. Any integer value should be rendered as `"N Beds"`.
- **Carousel images:** `images` contains asset names from `Tahudu/Assets/Assets.xcassets/Carousel Images` (`FirstImage`, `SecondImage`). Use these to drive the image carousel.
- **Tags:** `tags` drives the badges on top of the image (`VERIFIED`, `NEW CONSTRUCTION`, `LIVE VIEWING`). Feel free to introduce an enum to map from the raw values to UI.
- **Relative dates:** `publishedAt` is an ISO-8601 timestamp; compute a relative label such as “Published 3 days ago”.
- **Last contacted:** `lastContactedAt` is nullable. Only show the yellow “Last contacted …” banner when a value is present.

- **Contact options:** `contactOptions` indicates which contact buttons to show for each listing (phone, email, WhatsApp).
- **cURL Example:** You may use this `cURL` example to fetch the response to fill-up the data

```
curl -X GET "https://simplejsoncms.com/api/m6nfoc4jlw"
```

> **Important**
>
> Please refrain from using 3rd party libraries

Task 3 – Favourites and filtering

Add **local favouriting** to the Search screen and a way to filter by favourites.

Requirements

1. Tapping the heart icon on a listing card **toggles** it as a favourite.
2. Favourites are persisted **locally.**
3. Add a filter control on the first screen (the Search screen) that, when active, shows **only favourited listings.**
4. The filter state should be clearly visible so the user knows when they are viewing only favourites.

Notes

- **Architecture:** Decide where the favouriting logic should live (view, view model, data layer, etc.) and structure your code accordingly.

- **Heart icon state:** The heart should visually reflect the current favourite state (e.g. filled vs outline).
- **User experience:** Feel free to add small UX touches (animations, empty-state messaging) as long as the core behaviour is clear.

Bonus Task – Refactor the Settings screen

The code within Screens/Settings could be written much nicer. Your task is to clean it up. 🧹

We will evaluate:

- **How you are tackling the refactor**
- **Outcome of the refactor**

> 🖊 **Note**
>
> Even if you didn't finish it, just writing comments over what you would've intended here and how should be enough

---

Sending the project file back in

Once you are done with the exercises (within the **3-days** window), please share with us back the GitHub Repo you implemented the task on
